### **Abstract**

This study focuses on adoption of simulation system in rapidly changing technology and information flow. Given the prevalent popularity of simulation system, it is important to understand and adopt simulation system to develop future educational plans. This paper addresses that how simulation system enhances student collaborative learning and learner performance using Technology Acceptance Model (TAM). Results were analyzed using Structure Equation Modeling (SEM) technique; this study established that perceived usefulness, perceived ease of use, and perceived enjoyment all have a significant positive relationship with simulation system. The results indicate that simulation system serves as a dynamic tool to accelerate the progress of learning environments by encouraging collaboration and communication among students which strengthen their learning abilities and increase performance because students practically perform all the theories in a risk-free environment. In the competitive world, simulation system should be implementing at education level so that students can learn more before entering into a real-life career.

Keywords; Simulation system, Learning performance, Technology Adoption Model, Collaborative Environment, Usefulness, Enjoyment

## **Introduction**

Learning methods have changed, they have moved from traditional teaching model to learner-centered model that involves the learner in an active role (Garris, Ahlers, & Driskell, 2002). Now methods of learning are shifting from learning by listening to learning by doing. Kolb(1984) defined Experimental Learning Theory (ELT) that individual's learning process is the combination of experience, cognition, behavior, and perception. Use of simulation system (games, applications, and situation) has grown significantly over the last 20 years, that enhances the learner's capability to solve the problems (.Douglas, Miller, Kwansa, & Cummings, 2007; Jones, 1998; Rosen, 2008).The simulation system is an artificial environmental situation in which learners perform their duties in the real world scenarios (Gredler, 2004; Jones, 1998). Interacting with one another is a collaboration; it the fact that cooperation enhances knowledge, resources, and capabilities to perform tasks. A number of researchers found that collaborative learning has a significant positive effect not only on the academic performance of the student (Bossert, 1988; Cohen, 1994; Johnson, 1984), but also supportive in learning psychological and social aspects (Kreijns, Kirschner, Jochems, & Buuren, 2007; Sadeghi & Kardan, 2015). Researchers have agreed that simulation system enhances collaboration and performance of the students. To have learner's maximum attention towards the task, it is necessary to indulge learners in enjoyment related activities. Bostan (2009) and Bruner and Kumar(2005) added the variable of perceived enjoyment in TAM to measure consumer's internet use.

This study examined the perceived learner performance from the use of simulation system in a collaborative environment using Technology Adoption Model (TAM). In previous studies, TAM was used to measure the intention to adopt the simulation.

## **Model Adoption**

Technology Acceptance Model (TAM) proposed by (Davis, 1989) and commonly used theory on the practice and acceptance of new technology (Cheung & Vogel, 2012; Jan & Contreras, 2011). Technology Adoption Model (TAM) is multi-dimensional model which is used in different fields to analyze and interpret research results i.e. pure-sciences (Chaurasia, et al., 2016), operation research (Chena & Ma, 2016), computer sciences (Chuah, Rauschnabel, Krey, Nguyen, Ramayah, & Lade, 2016), public health(Zakaria & Yusof, 2016), environmental sciences (Rai & Robinson, 2015), industrial engineering(Guo & Zhu, 2016), social sciences (Arifina & Frmanzah, 2015)and many more. Many research studies applied TAM to envisage the user intent to adopt technology (Pando-Garcia, Periañez-Cañadillas, & Charterina, 2015). These studies proved that this model considerably influence the technology adoption. Sukkar & Hasan (2005) and Benbasat & Bark (2007) inquired about the appropriateness of TAM model in case developing countries and students intention in adopting technology and propose modification in TAM model for making it more appropriate in this case. However, no studies have been found in the previous literature to explore the use of simulation system for collaborative learning to enhance learner's performance using modified TAM

Technology Acceptance Model (TAM) is derivative of Theory of Reasoned Action (Ajzen & Fishbein, 1980), which illustrate that the behavior of individual changes after adoption of new technologies. TAM has basically two main constructs: perceived usefulness and perceived ease of use, which assist user to build the intention to adopt new technology. For this study, perceived enjoyment is also used because interesting and entertaining features of using simulation systems. As, earlier studies performed by Csikszentmihalyi (1975) and Moon and Kim(2001) used perceived enjoyment as construct in modified TAM. For this study, perceived enjoyment, perceived usefulness and perceived ease of use pleasure to investigate the impact simulation system on collaborative learning and learner’s performance using modified TAM

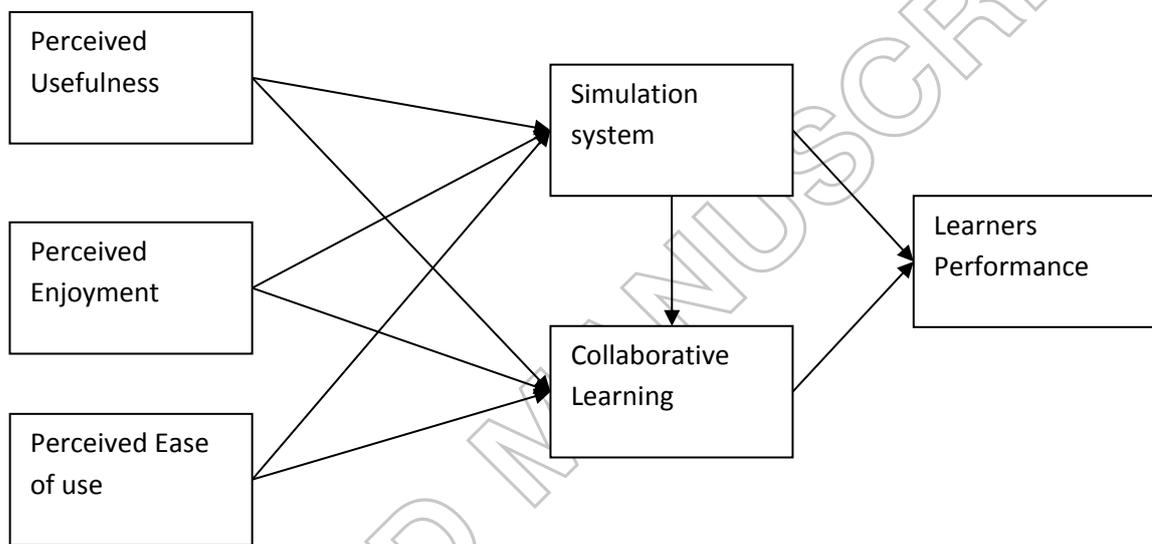

Figure 1 Technology Acceptance Model (Davis, 1989)

### Perceived Usefulness

Perceived usefulness is defined as “the degree to which a person believes that using a particular system may enhance his or her job performance” (Davis, 1989). Perceived usefulness is the main construct of Technology Adoption Model (TAM), which predicts the behavioral intention of a person to use technology (Davis, Bagozzi, & Warshaw, 1992; Hart & Porter, 2004). According to Alrafi (2007), this construct can predict system acceptance, user intentions and continual use of the system. Perceived usefulness has frequently been used by many researchers (Dulcica, Pavlich, & Silicc, 2012; Liu & Huan, 2015; Alrafi, 2007; Fagan, Kilmon, & Pandey, 2012) they argue that perceived usefulness enhances attitude and encourage people to adopt simulation system in future for better understanding and learning. Researchers explore that there is the positive impact of perceived usefulness on user satisfaction. In this research, perceived usefulness is viewed as an instrumental need to accomplish tasks like learning, education, research and other experimental tasks (Bhattacharjee, 2001; Chea & Luo, 2008; Hong, Thong, & Tam, 2006; Thong, S.-J.Hong, & Tam, 2006). By above discussion following research hypothesis is suggested;

H1: There is a significant positive relationship between perceived usefulness and Simulation system

H2: There is a significant positive relationship between perceived usefulness and collaborative learning

### **Perceived ease to use**

Perceived ease of use is defined as “the degree to which a person believes that using a particular system would be free of effort” (Davis, 1989). From the definition, ease means freedom with great effort or difficulty. The effort is a limited resource which a person can allocate for activities for which he/she is answerable (Radner & Moran, 1975). If the use of the system is easy, people are willing to learn it and have positive intention to use in future (Chiu & Wang, 2008). Designing of games or system should be user-friendly and easy to use, it has a positive impact on the intention of individuals to learn from that system (Hamida, Razak, Bakar, & Abdullah, 2016). Perceived ease of use will affect the individual’s satisfaction which leads user’s loyalty i.e. repeated usage or continuous buying of product (Zhao, Chen, & Wang, 2016). There is a non-linear relationship between the ease of use and behavior intention of individual in case of simulation system (i.e. sports, simulation system, Strategic games, adventure and fighting games). If simulation system is easy to use, it has no challenging effect and user may get bored and if the system is too difficult to use, the user may get offended and not willing to learn from it. If the system is too easy or too difficult learner is unable to learn from simulation system (Davis & Lang, 2012).

H3: There is a significant positive relationship between perceived ease of use and simulation system

H4: There is a positive significant relationship between perceived ease of use and collaborative learning.

### **Perceived Enjoyment**

Perceived enjoyment is defined as “the degree to which the activity of using technology is perceived to be enjoyed in its own, right apart from any performance consequences that may be anticipated” (Davis, Bagozzi, & Warshaw, 1992). Perceived enjoyment has a significant positive effect on individual behavior towards his/her task (Pe-Than, Goh, & Lee, 2014; Heijden, 2003; HsuL & Lin, 2008) concluded that perceived enjoyment has a positive significant behavioral intention to use the hedonic system. According to Davis et al. (1992), perceived enjoyment is similar to intrinsic motivation which boosts up the performance of an individual. Venkatesh & Speier (2000) compared two methods of training, i.e. traditional training methods (lectures, theoretical knowledge) and simulation-based training methods (simulation system) and they found simulation system based training enhances intrinsic motivation which results in the behavioral intention of the individual in gaining knowledge from this system again and again. Hung, Tsai, & Chou (2016) stated that users perceive less enjoyment when they interact with a system having utilitarian benefits as compared to the system which has high hedonic characteristics (Nysveen, Pedersen, & Thorbjørnsen, 2005;

Xu, Lin, & Chan, 2012). There is still a question that simulation system provides learner enjoyment and helps them in collaborative learning. From the above discussion, following research hypothesis is proposed;

H5: There is a significant positive relationship between perceived enjoyment and simulation system

H6: There is a positive significant relationship between perceived enjoyment and collaborative learning.

### **Simulation system**

The simulation system is designed by constructivist learning theory, as user learn or constructs new knowledge from his/her conceptual understanding (Vygotsky, 1978; Dewey, 1938). Simulation is a reliable and exciting system which provides students learning based experience which motivates and encourage them to learn. This system offers student's information-rich environment where they work together in groups, brainstorm and share their ideas and make a decision in certain situations while working in the risk-free but practical environment. Simulation system has many depended variables, the main aim of simulation system is that all participants have some roles and all have to react according to the situation and give their feedback to achieve the desired goal (Gredler, 2004). Simulation system has some set of rules and roles which students need to follow which gave them an essence of working in the real based scenario but risk-free (Leemkuil, Jong, & Ootes, 2000).

Simulation systems are based on theories and application which need to implement by students to enhance their learning performance by engaging themselves in a real situation. Mawhirter & Garofalo (2016) stated that simulation systems are the creative and innovative way to increase student's interest in learning. Simulation-system not only helps students in reducing stress but also assist in knowledge retention (Popil & Dillard-Thompson, 2015). According to Blakely, Skirton, Cooper, Allum, & Nelmes (2010) simulation system in education helps the student to enhance learning with enjoyment, interest and interacting with other students. According to (Thavikulwat (2004), simulation system let students step into the case with the complicated real-life situation. Gredler (2004) defines essential characteristics of simulation: (1) student actively interact with complicated real-life condition; (2) clear rules, regulation, responsibilities, and position is defined to student; (3) students can apply different strategies by keeping themselves within limitations outlined earlier;(4) problems and situations changes while performing the simulation system task so that students can deal with changes. Hughes & Scholtz (2015) stated that simulation system provides students an experimental way of learning, simulation system creates opportunities for students to gain more knowledge by keeping themselves in a real-world context. Students digest the knowledge which they have experienced through simulation system. Simulation system can be classified as gaming, training, discrete, continuous or combined events, workshops and modeling (Lean, Moizer, Towler, & Abbey, 2006).

The scope of simulation system is in many fields like life sciences, information technology, mathematics, business studies, physics, aerospace, engineering, language, culture, emergency

studies and many more (Chittaro & Sioni, 2015; Ebner & Holzinger, 2007; Mawhirter & Garofalo, 2016; Strahilova & Damrathb, 2015). Conventional teaching methods like lectures, case studies and discussions provide student theoretical insights of topics but lack in providing real-world experience and feel of actual practices and processes. Simulation system plays a role in the development of student's learning skills, as the student has to make decisions by looking at the environment and other student's decision-making choices (Lainemaa & Nurmib, 2006). Simulation system works as the bridge between the theory and practice, which helps the student to enhance their technical and critical thinking skills (Bell & Loon, 2015). Simulation system increased motivation (Frapp, 1997), experimental learning (Adobor & Daneshfar, 2006), develop critical thinking (Doyle & Brown, 2000), work on real-world scenario but in the risk-free environment (King & Newman, 2009), develop time management and working in team skills (Doyle & Brown, 2000).

H8: There is a significant positive relationship between simulation system and learner performance

### **Collaborative Learning**

Collaborative learning can be defined as two or more people working together to create or achieve a particular objective. In many fields or disciplines including business, management, medicine, sports, entertainment and much more, collaborative learning is permitted (Hmelo-Silver, Chinn, Chan, & O'Donnell, 2013). Collaborative learning encourages institutes to think out of the box and also help people to learn and innovate (Lytras, Mathkour, Al-Halabi, Yanez-Marquez, & Siqueira, 2015). There is a difference between collaborative learning and cooperative learning; their outcome of performance and learning also differ, in cooperative learning members in group divide or split their work into subtasks and then join their work to form a result (Sadeghi & Kardan, 2015). According to Lytras, Mathkour, Al-Halabi, Yanez-Marquez, & Siqueira (2015), collaborative learning is multi-dimensional; the world is measuring the performance of the students through static, monolithic approach. (Zhuhadar, Yang, & Lytras (2013); Dascalua, Bodeab, Moldoveanuc, Mohora, Lytrasd, and Pablose (2015) the world should adopt new grading system in which students should not only evaluated by memorization of concepts but also tested on critical collaborative thinking. Simulation-based collaborative learning enhances students' learning in the real world scenario. It is observed that students show better performance when they collaboratively learn through simulation system as compared to the non-simulation system (Ke & Carafano, 2016). From above, following hypothesis is presented:

H9: There is a significant positive relationship between collaborative learning and learners' performance

### **Learner performance**

Many studies show that simulations improve the learning performance of individuals (Shapiro, et al., 2004; Gaba, Howard, & Fish, 2001; Grantcharov, Kristiansen, Bendix, Bardram, Rosenberg, & Funch-Jensen, 2004). Simulation system prepares learners to deal

with unanticipated events, which in turn increase their confidence in real-world work performance. Lateef (2010) simulation system is a multidisciplinary system in which individuals with different technical responsibilities collaborate with each other to solve the given problem efficiently and effectively. Simulation system provides learner an eye to recognize the problem and adopts a proactive approach to solving it. According to Junco, Heiberger, & E. Loken (2011), there is a significant positive relationship between collaborative learning, learning performance and engagement with work. Learners can learn very fruitful concepts by indulging themselves in simulations. Madge, Meek, Wellens, and Hooley (2009) urged that use of this technology can work as a bridge between learners, instructors and other participants, where all can learn from each other by sharing their ideas and experiences.

### **Research Methodology and Data Collection**

This research measures the effect of perceived enjoyment, collaborative learning from simulation system which results in learner performance using Technology Acceptance Model. To perform statistical analysis, data were collected from multi-national undergraduate, graduate and post-graduate students of four different disciplines i-e business management students, pure sciences, information technology and engineering from University of Science and Technology China, Tsinghua University and Shanghai Jiao Tong University, who knows stimulation games/system. 400 questionnaires were circulated among students out of which 360 surveys were found accurately filled. Questionnaire was adapted from different research articles such as perceived usefulness and perceived ease of use (Davis, 1989) perceived enjoyment(Moon & Kim, 2001) collaborative learning (Fraser & Treagust., 1986) learner performance (Nale, Rauch, Wathen, & Barr, 2000) with modifications of words and sentences in accordance with the current study. Seven Likert scales are used where one strongly disagrees, four neutral and seven strongly agree.

### **Data Analysis**

Data is collected from the classified respondents, according to gender, education, the field of study and the students who know simulation system/systems. Gender is classified as male and female; respondents were 55.8% and 44.2% respectively. Education level was classified as under-graduate, graduate and post-graduate, respondents were 26.38%, 28.05%, and 45.55% respectively and respondents of the field of study were 35.27 management sciences, 19.72 pure sciences, 18.61 information technology, 20.83 Engineering and 20% others shows in table#1. These all respondents have knowledge and at-least use simulation system for one time.

<b>Demographics</b>	<b>Frequency</b>	<b>Percentage</b>
<b>Gender</b>		
Male	201	55.8
Female	159	44.2
<b>Educational Level</b>		
Under-Graduate	95	26.38
Graduate	101	28.05
Post- Graduate	164	45.55
<b>Field of Study</b>		
Management Science	127	35.27
Pure Sciences	71	19.72
Information Technology	67	18.61
Engineering	75	20.83
Others	20	0.55

Table 1 Demographics of respondents

For the examination of measurement and structural model, structural equation model (SEM) employing the AMOS-21. AMOS is a powerful technique which coalesces Principle component Analysis and regression simultaneously from the assessment of measurement and structural model. AMOS is better in dealing with evaluation of formative measurement and in testing moderating relationship. AMOS software not only can originate developmental model for a latent variable but also show the graphical representation of interpretation. For these strong reasons, AMOS-21 software is used for the examination of measurement and structural model (Anderson & Gerbing, 1988).

#### Measurement Model

For the examination of the measurement model, stepwise processes were followed. First, Explanatory factor analysis (EFA) was performed to examine factor loading using SPSS whether the benchmark values are above 0.4 (Hair, Anderson, Tatham, & Black, 1998). EFA is used to confirm the accuracy of items and factors are matching and are ready for factor relationship analysis. Results verify the validity of hypothesized model as the indices of factor loading are between (0.719-0.902). All values of indices are above the recommended values which shows lack of concern about cross-loading except for three items which were excluded from the data.

Next step, to perform CFA tests to measure the convergent validity, factor loading, Cronbach's Alpha, Average Variance Extracted (AVE) and composite reliability (CR) (Flynn, Sakakibara, Schroeder, Bates, & Flynn, 1990). CFA results indicate that loading of all items is above 0.7. To examine the reliability and validity of data tests like Cronbach Alpha, AVE and CR values are extracted using SPSS. Cronbach Alpha and CR values should be above than 0.7, which make data considerable for further analysis. Results indicate that Cronbach Alpha values are between (0.778- 0.932) and CR values are between (0.784-0.909). AVE value should be equal or higher than 0.5. In this research study, AVE value ranged between (0.554-0.728). Results indicate that there are no convergent validity and reliability issues with data.

<b>Constructs</b>	<b>Factor Loading</b>	<b>CR</b>	<b>AVE</b>	<b>Cronbach's Alpha</b>
<b>Use of Simulation</b>		0.889	0.728	0.889
SIM1	.860			
SIM2	.859			
SIM3	.824			
<b>Perceived Usefulness</b>		0.796	0.568	0.789

PEU2	.875			
PEU3	.854			
PEU4	.878			
<b>Perceived Enjoyment</b>		0.831	0.623	0.827
PEN1	.784			
PEN2	.815			
PEN3	.795			
<b>Collaborative Learning</b>		0.825	0.611	0.823
CL1	.807			
CL2	.762			
CL3	.784			
<b>Perceived Learning</b>		0.784	0.554	0.778
PEL1	.770			
PEL2	.842			
PEL3	.719			

Table 2 Result of Confirmatory Factor Analysis

Next step is to measure the discriminant validity of the hypothesized measurement model; it is measured by comparing the AVE Square root of each construct with inter-correlation of constructs. Values of AVE square root should be higher than inter-correlation of constructs (Hair, Anderson, Tatham, & Black, 1998). Results indicate discriminant validity is established. Hence data is fit for further analysis of the structural model. Meanwhile, we also measure variance inflation factor (VIF) to examine the multi-collinearity concerns. Results show the values of VIF ranges between 1.53- 2.715 which is below the threshold value of 10 (Hair, Anderson, Tatham, & Black, 1998). Thus results show no multi-collinearity concerns.

	M(SD)	PEL	PEU	SM	CL	PEN	PU
PEL	4.30(1.38)	<b>0.744</b>

### Measurement and structural Model Analysis

Structural Equation Modeling (SEM) has become one of the important techniques for researchers across disciplines, and social sciences researchers are also adopting these methods to validate their research results (Hooper, Coughlan, & Mullen, 2008). To see the model fit researchers need to examine fitness indices like chi-square, GFI, AGFI, TLI, CFI, and RMSEA. Barrettx (2007) and Hu & Bentler (1999) recommend value for goodness of model Chi-square should not be less than 2.0 nor higher than 5.0 (Tabachnick & Fidell, 2007) depending upon the sample size. RMSEA value should be less than <0.10 (Arbuckle, 2003) and according to Stegier (2007) upper limit is 0.07 and according to McQuitty (2004) to upper limit should be less than 0.08. According to Miles & Shevlin (2007) GFI and AGFI indices values can be >0.90 and >0.80 respectively (Arbuckle, 2003). Hu & Bentler (1999) and Arbuckle (2003) states CFI and TLI indices values can be >0.90 and > 0.95 respectively. In this research paper, SEM technique is used along with AMOS 24 and CFA (Confirmatory Factor Analysis) to measure the goodness-of-fit model using indices. According to above references indices for this research show the goodness-of-fit model where values of chi-square, GFI, AGFI, CFI, TLI, and RMSEA are correct shown in table#4.

Model	$\chi^2$	df	$\chi^2/df$	GFI	AGFI	CFI	TLI	RMSEA
Base	308.954	134	2.306	.917	0.882	0.943	0.955	0.60

Table 4 Fitness of Measurement Model

Model	$\chi^2$	df	$\chi^2/df$	GFI	AGFI	CFI	TLI	RMSEA
Base	1391.798	488	2.852	.862	0.935	0.954	0.952	0.061

Table 5 Fitness of Structural Model

### Hypotheses Testing

After examining the validity of the structural model next step is to test hypotheses relationship using SEM fig 2. Results show that perceived usefulness ( $\beta=.343$ ,  $p<.001$ ), perceived ease of use ( $\beta = 1.60$ ,  $p=.001$ ) and perceived enjoyment ( $\beta =.213$ ,  $p <.001$ ) have the positive effect of the use of simulation. Therefore H1, H2, and H3 are supported. Similarly perceived usefulness, perceived ease of use and perceived enjoyment have the positive effect on collaborative learning. Therefore H4, H5, and H6 are supported. Use of simulation system has ( $\beta =.249$ ,  $P<.001$ ) which shows the use of simulation system has a positive impact on collaborative learning and H7 is supported. Use of simulation system and collaborative

learning has ( $\beta = .174, p < .001$ ) and ( $\beta = .206, p < .001$ ) respectively which shows the use of simulation system and collaborative learning has a positive impact of learning performance of student; thus H8, H9 are also supported table# 5.

Hypotheses	Independent	Relationship	Dependent	Estimate	S.E.	CR	P	Result
H1	PEU	→	SM	.160	.049	3.230	.001	Supported
H2	PEN	→	SM	.213	.051	4.165	***	Supported
H3	PU	→	SM	.343	.047	7.258	***	Supported
H4	PEU	→	CL	.313	.047	6.666	***	Supported
H5	PEN	→	CL	.150	.049	3.057	.002	Supported

Table 6 Hypotheses Testing Results

Figure#3 shows that 28.7% of variance exists in use of simulation system and 37.3 % of variance exists in collaborative learning, and 28.9% of variance exists in learning performance of students.

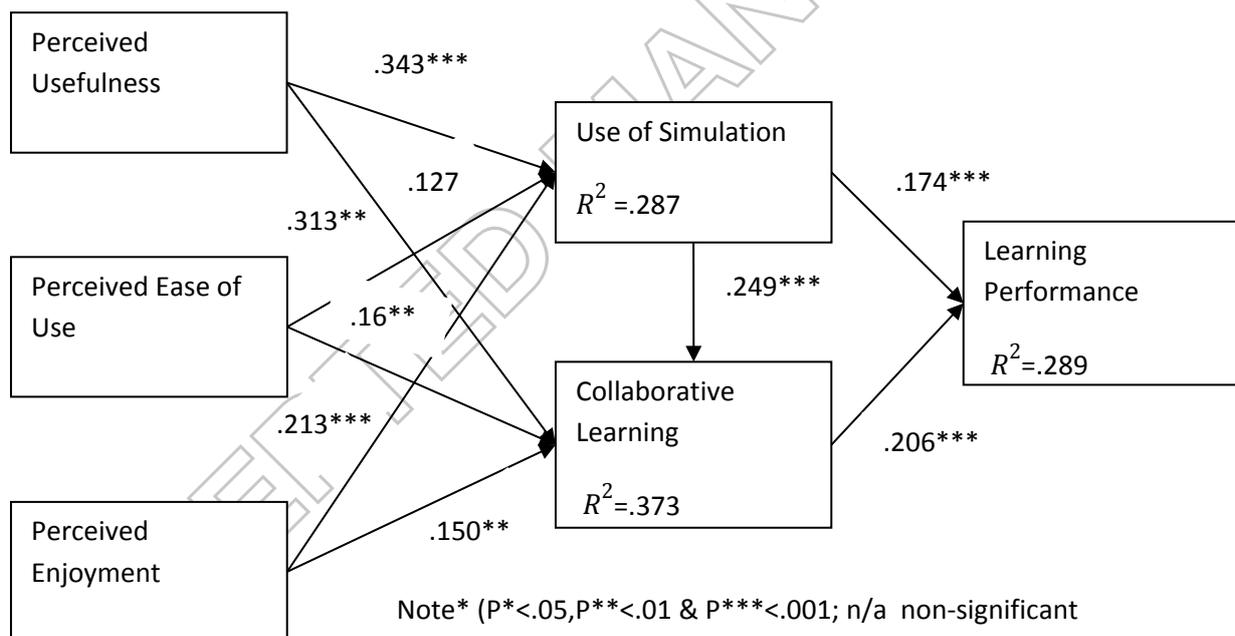

Figure 2 Result of tested model

## Conclusion and Future Implication

The primary aim of this study is to examine the impact of simulation system on the learning performance of the students. As traditional methods of teaching just focus on class lectures, giving lectures on theories and concepts. Simulation systems allow students to work practically but in a risk-free environment. The research was performed on students who

belonged to different fields to determine the learning performance of the students with a simulation system. The result of the study examined that student learning performance improves by using simulation system, by involving them in collaborative studies in groups, easy to use system, useful and fun learning environment. In this paper, Technology Adoption Model (TAM) is used to examine learning performance of the students who applied or have some know how about simulation system. Data was collected from students of different fields like management sciences, pure sciences, information technology, and engineering; results show that simulation is useful and easy system and the element of fun also help them to learn different concepts efficiently and efficiently. This paper also examined that collaborative environment enhances the learning performances of the students. Hence the all hypotheses were supported.

Simulation system provides a collaborative environment which enhances learning performance of students. The simulation system is an opportunity for students to a built number of skills to work in groups like leadership skills, teamwork skills, conflict management skills, and negotiations skills and learn from each other. According to Wood, Beckmann, & Birney (2009), learning leadership skills, teamwork skills, conflict management skills, and negotiations skills helps students in their practical workplace where people from different areas, culture and personalities are working together. Simulation system allows students to link theory with practice. Simulation system can enhance students learning performance by adopting different strategies for the implementation of various approaches and logic. Simulation systems allow students to learn how they can apply these theories and concepts in the practical workplace, which could generate better results for them.

Simulation-based studies are a useful, easy and fun way of learning, which help students to think critically. There is a need to shift from traditional model of instruction (for examples lectures) to learner based models, that support students to learn more while engaging themselves in the practical implication of theories. Simulation-based studies are considered as the supplement in classrooms learning, that enhances collaboration among students, and they involve and help each other in the learning process (Otting, Zwaal, & Gijsselaers, 2009). Educators should put their efforts to generate student's attention and interest towards the studies. It is essential for educators to use simulation-based learning method so that students can get a better understanding of theory in a comfortable and fun environment. According to Pratt & Hahn (2016), fun elements maximize the learning process. Educators should take feedback from students regarding usefulness, easiness, and learning, so that course can be modified accordingly.

There are lots of challenges in the implementation of simulation-based learning. There is a need to train educators and instructors to learn new technologies and method of teaching so that they can enhance student's creativity and learning performance. People are always reluctant to adopt a new way of doing things, so there is a need to create awareness of simulation system adoption and its benefits for both students and instructors. Future research can be done in different departments to test the change in intention and attitude to adopt the field of study in which they used simulation system. How simulation system motivates and encourages students to choose the field of education in which they use simulation system.

## **Public interest statement**

In today's changing and dynamic environment and economic conditions, there is a need of re-orientation and modification of educational programs, where learning progression should focus on strengthening knowledge and skills in accordance with needs and wants of the market. Conventional methods of teaching are not supportive in coping with unpredicted market dynamics and complex organization conditions. It is the requirement of time to alter teaching and educational methods. Now many universities are hiring professor, whose main task is not only to give knowledge but also to motivate students to choose their professions according to their learning. New generation is brought up with mobiles devices, access to internet, laptops, and video games. Educational system should be modified and simulation method of teaching should be adopted in accordance with current generation habits and pleasing method of learning.

## **Author statement**

Salman Zulfiqar is currently a PhD candidate at University of Science and Technology of China, School of Public Affairs. He completed his Master of sciences degree of Umea University, School of Business and Economics. His research interests include Social media and public administration, online student engagement and collaborative learning, social capital, and entrepreneurial learning, social entrepreneurial readiness and learning. He is the corresponding author for this research paper and can be contacted at [sa572599@mail.ustc.edu.cn](mailto:sa572599@mail.ustc.edu.cn) and [salmanzulfiqar@gmail.com](mailto:salmanzulfiqar@gmail.com)
