On asymptotic stability of a class of time–delay systems

Serbun Ufuk Değer
d and Yaşar Bolat

Abstract: In this paper, we give some new necessary and sufficient conditions for the asymptotic stability of a class of time–delay systems of the form

\[ x'(t) + (1 - a)x(t) + A(x(t - k) + x(t - l)) = 0, \quad t \geq 0, \]

where \( a \) is a real number, \( A \) is a \( 2 \times 2 \) real constant matrix, and \( k, l \) are positive numbers such that \( k > l \).

Subjects: Advanced Mathematics; Applied Mathematics; Dynamical Systems

Keywords: asymptotic stability; delay differential equations; characteristic equation

1. Introduction

In this paper, we study the asymptotic stability of the solutions of time–delay systems of the form

\[ x'(t) + (1 - a)x(t) + A(x(t - k) + x(t - l)) = 0, \quad t \geq 0, \]

(1.1)

where \( a \) is a real number, \( A \) is a \( 2 \times 2 \) real constant matrix, and \( k, l \) are positive numbers such that \( k > l \). Time–delay systems are a type of differential equations in which the derivative of the unknown function at a certain time is given in terms of the values of the function at previous times. Also, they are called delay differential equations, retarded differential equations or differential–difference equations. On the other hand, since asymptotic stability is an interdisciplinary material, the asymptotic stability of these systems has a wide range of applications as biology, physics and medicine. Thus, it is useful to use qualitative approaches to investigate the asymptotic stability of these systems. Our research represents a generalized method for describing the asymptotic stability of systems within of science branches such as biology and physics.
physics, and medicine. For instance, Naresh, Tripathi, Tchuenche, and Sharma (2009) formulated a nonlinear mathematical model to study the framework of disease Epidemiology. As another example Ikeda and Watanabe (2014) were investigated the stochastic differential equations and diffusion processes in their study about physic. Kruthika, Mahindrakar, and Pasumarthy (2017) were studied stability analysis of nonlinear time-delayed systems with application to biological models. They analyzed the local stability of a gene-regulatory network and immunotherapy for cancer modeled as nonlinear time-delay systems.

Many authors have also focused on the asymptotic stability of time-delay systems. Some important studies about related subject can be examined from the below authors: Bellman and Cooke (1963), Cooke and Grossman (1982), Cooke and van den Driessche (1986), Stepan (1989), Freedman and Kuang (1991), Kuang (1993), Ruan and Wei (2003), Elaydi (2005), Matsunaga (2008), Smith (2010), Gray, Greenhalgh, Hu, Mao, and Pan (2011), Khokhlova, Kipnis, and Malygina (2011), Xu (2012), Hrabalova (2013), Nakajima (2014), Liu, Jiang, Shi, Hayat, and Alsaeedi (2016), and Li, Ma, Xiao, and Yang (2017). Also, an equation which is the special case of our system which is investigated by Kuang (1993) and he demonstrated that the zero solution of the delay differential equation with two delays of the form

\[ x(0) + q(x(t - k) + x(t - l)) = 0, \quad t \geq 0, \] (1.2)

where \( k \geq 0, l \geq 0 \) and \( q \) is positive constant and is asymptotically stable if and only if

\[ 2q(k + l) \cos \left( \frac{k - l}{k + l} \pi \right) < \pi. \] (1.3)

2. Preliminaries

It is known that for the time-delay equations, an equation is asymptotically stable if and only if all roots of the associated characteristic equation have negative real parts. Stability analysis, however, does not require the exact calculation of the characteristic roots; only the sign of the real part of the critical root must be determined. This analysis can be performed by D-subdivision method (see, e.g., Insperger & Stépán, 2011; Stepan, 1998), which gives a necessary and sufficient condition for stability based on the coefficients of the characteristic equation. The aim of this paper is to obtain new results for the asymptotic stability of zero solution of system (1.1), while the characteristic equation of system (1.1) has roots on the imaginary axis when \( A \) is a constant matrix. If we obtain \( x(t) = Py(t) \) for a regular matrix \( P \) in (1.1), then we have the following system:

\[ y'(t) + (1 - a)y(t) + P^{-1}AP(y(t - k) + y(t - l)) = 0, \quad t \geq 0. \]

Thus, matrix \( A \) can be given one of the following two matrices in Jordan form [7]:

(I) \( A = \begin{pmatrix} q_1 & r \\ 0 & q_2 \end{pmatrix} \), \( q_1, q_2, \) and \( r \) are real constants,

(II) \( A = q \begin{pmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{pmatrix} \), \( q, \theta \) are real constants and \( |\theta| \leq \frac{\pi}{2} \).

Here we consider the case (II), the other case should be considered similarly. The characteristic equation of system (1.1) is given as

\[ F(\lambda) := \det \left( \lambda I_2 + (1 - a)I_2 + A \left( e^{-\lambda k} + e^{-\lambda l} \right) \right) = 0, \] (2.1)

where \( I_2 \) is the 2 \( \times \) 2 identity matrix. Using (2.1), we obtain

\[ F(\lambda) = \left( \lambda + (1 - a) + q \cos \theta \left( e^{-\lambda k} + e^{-\lambda l} \right) \right)^2 + \left( q \sin \theta \left( e^{-\lambda k} + e^{-\lambda l} \right) \right)^2 \]
\[
\lambda + (1 - a) + q\cos(\theta)(e^{-i\delta k} + e^{-i\delta l}) - i\sin(\theta)(e^{-i\delta k} + e^{-i\delta l})^2 = 0.
\]

If we let
\[
f(\lambda) = \left(\lambda + (1 - a) + q(e^{-i\delta k} + e^{-i\delta l})\right),
\]
then we have
\[
F(\lambda) = f(\lambda)f(\bar{\lambda}),
\]
where \(\bar{\lambda}\) is the complex conjugate of any complex \(\lambda\). Note that \(f(\lambda) = 0\) implies \(f(\bar{\lambda}) = 0\).

### 3. Some auxiliary lemmas

In this section, we will investigate the distribution of the zeros of the characteristic equation of system (1.1). Thus, we state and prove some basic results on the roots of the characteristic equation of system (1.1).

**Lemma 1** (Stepan, 1989) The zero solution of (1.1) is asymptotically stable if and only if all the roots of equation
\[
f(\lambda, k, l) = \lambda + (1 - a) + q(e^{-i\delta k} + e^{-i\delta l}) = 0.
\]

lie in the left half of the complex plane.

Since \(f\) is an analytic function of \(\lambda, k\) and \(l\) for the fixed numbers \(a, q\) and \(\theta\), one can regard the root \(\lambda = \lambda(k, l)\) of (3.1) as a continuous function of \(k\) and \(l\). The next lemma plays very important role for the main theorem.

**Lemma 2** (Cooke & Grossman, 1982) As \(k\) and \(l\) vary, the sum of the multiplicities of the roots of (3.1) in the open right half-plane can change only if a root appears on or crosses the imaginary axis.

Consequently, we claim that (3.1) has only imaginary roots \(\pm i\omega\). We will determine how the value of \(k\) and \(l\) change as Equation (3.1) has roots on the imaginary axis. Now, we can write the characteristic Equation (3.1) as follows:
\[
\lambda + (1 - a) + q(e^{-i\delta k + i\theta} + e^{-i\delta l + i\theta}) = 0.
\]

At the same time, we take \(\lambda = i\omega\) such that \(\omega \in \mathbb{R}\). Firstly, since \(f(0) = (1 - a) + 2qe^{i\theta} \neq 0\), we see that \(\omega \neq 0\). For \(\omega \neq 0\), we obtain
\[
f(i\omega) = i\omega + (1 - a) + q(e^{-i\delta k + i\theta} + e^{-i\delta l + i\theta}) = 0.
\]

Using the real part and the imaginary part of (3.3)
\[
\omega = q(\sin(\omega k - \theta) + \sin(\omega l - \theta)),
\]
\[
a - 1 = q(\cos(\omega k - \theta) + \cos(\omega l - \theta)),
\]
which is equivalent to
\[
\omega = 2q \sin\left(\frac{\omega(k + l)}{2} - \theta\right) \cos\left(\frac{\omega(k - l)}{2}\right).
\]
\[ a - 1 = 2q \cos \left( \frac{\omega(k + l)}{2} - \theta \right) \cos \left( \frac{\omega(k - l)}{2} \right), \]  

(3.7)

is obtained.

**Lemma 3.** Suppose that, \( q > 0 \) and \( 0 < \theta \leq \frac{\pi}{2} \). Let \( \lambda = i\omega \) be a root (3.1) where \( \omega \in \left( \frac{\pi}{2\gamma}, \frac{\pi}{\epsilon} \right) - \left\{ \frac{n\pi + \epsilon \omega}{k + l} \right\} \) for \( n = 0, 1, 2, \ldots \), then the following conditions hold:

(i) If \( \left( 2q \cos \left( \frac{\omega(k - l)}{2} \right) \right)^2 - (a - 1)^2 \leq 0 \), then there exists no real number \( \omega \).

(ii) If \( \left( 2q \cos \left( \frac{\omega(k - l)}{2} \right) \right)^2 - (a - 1)^2 > 0 \), then the real numbers \( \omega, q \) and the delays \( (k + l) \) are as follows:

\[ \omega = \pm \gamma = \pm \sqrt{\left( 2q \cos \left( \frac{\omega(k - l)}{2} \right) \right)^2 - (a - 1)^2}, \quad q = \frac{a - 1}{2 \cos \left( \frac{\omega k - \theta}{2} \right) \cos \left( \frac{\omega l}{2} \right)} \quad \text{and} \quad k + l = (k_n + l_n)^+ \quad \text{for} \quad n = 0, 1, 2, \ldots \]

\[ (k_n + l_n)^+ = \frac{2}{\gamma} \left\{ 2n\pi + \arccos \left( \frac{a - 1}{2q \cos \left( \frac{\omega(k - l)}{2} \right)} \right) + \theta \right\} \]

\[ (k_n + l_n)^- = \frac{2}{\gamma} \left\{ 2n\pi + \arccos \left( \frac{a - 1}{2q \cos \left( \frac{\omega(k - l)}{2} \right)} \right) - \theta \right\}, \]

and \( i\gamma \) or \( -i\gamma \) is a root of (3.1) for the sum of delays \( (k_n + l_n)^+ \) or \( (k_n + l_n)^- \).

**Proof.** By squaring both sides of (3.6) and (3.7), and adding them together, we obtain

\[ \omega^2 + (a - 1)^2 = \left( 2q \cos \left( \frac{\omega(k - l)}{2} \right) \right)^2. \]

(3.8)

If \( \left( 2q \cos \left( \frac{\omega(k - l)}{2} \right) \right)^2 - (a - 1)^2 \leq 0 \), then statement (3.8) implies \( \omega^2 < 0 \), contradicts with \( \omega^2 > 0 \). Since \( \omega \neq 0 \), condition (i) is verified; that is, (3.1) has no root on the imaginary axis for all \( k > l > 0 \).

On the other hand, if \( \left( 2q \cos \left( \frac{\omega(k - l)}{2} \right) \right)^2 - (a - 1)^2 > 0 \), statement (3.8) implies that

\[ \omega = \pm \sqrt{\left( 2q \cos \left( \frac{\omega(k - l)}{2} \right) \right)^2 - (a - 1)^2}. \]

(3.9)

If we let

\[ \gamma = \sqrt{\left( 2q \cos \left( \frac{\omega(k - l)}{2} \right) \right)^2 - (a - 1)^2}, \]

then we can write \( \omega = \pm \gamma \). By (3.7), we have

\[ q = \frac{a - 1}{\cos \left( \frac{\omega(k + l)}{2} - \theta \right) \cos \left( \frac{\omega l}{2} \right)} \]

Now, we will show that \( i\gamma \) is a root of (3.1).

In the case of \( \omega = \gamma \), since \( \cos \left( \frac{\omega(k + l)}{2} \right) > 0 \) for \( \omega \in \left( \frac{\pi}{2\gamma}, \frac{\pi}{\epsilon} \right) - \left\{ \frac{n\pi + \epsilon \omega}{k + l} \right\} \) and using (3.6)

\[ \sin \left( \frac{\omega(k + l)}{2} - \theta \right) > 0. \]

(3.10)
is obtained. Thus, we use (3.6) and (3.7), we have
\[
\frac{\omega(k + l)}{2} - \theta = 2n\pi + \arccos\left(\frac{a - 1}{2q \cos\left(\frac{\omega(k - 1)}{2}\right)}\right), \quad n = 0, 1, 2, \ldots,
\]
which yields \((k_n + l_n)^+\). Also, from (3.6) and (3.7), we obtain
\[
\sin\left(\arccos\left(\frac{a - 1}{2q \cos\left(\frac{\omega(k - 1)}{2}\right)}\right)\right) = \frac{\gamma}{2q \cos\left(\frac{\omega(k - 1)}{2}\right)}
\]
because of
\[
\arccos\left(\frac{a - 1}{2q \cos\left(\frac{\omega(k - 1)}{2}\right)}\right) = \begin{cases} 
\arcsin\left(\frac{\gamma}{2q \cos\left(\frac{\omega(k - 1)}{2}\right)}\right) & \text{if } a - 1 \geq 0 \\
\pi - \arcsin\left(\frac{\gamma}{2q \cos\left(\frac{\omega(k - 1)}{2}\right)}\right) & \text{if } a - 1 < 0.
\end{cases}
\]
Hence, for the case \(k + l = (k_n + l_n)^+\), \(i\gamma\) is a root of (3.1). Indeed,
\[
f(i\omega) = i\omega + (1 - a) + q\left(e^{i(\omega(k-1))} + e^{i(\omega l_k)}\right).
\]
\[
= i\sqrt{\left(2q \cos\left(\frac{\omega(k - 1)}{2}\right)\right)^2 - (a - 1)^2 + (1 - a) + 2q \cos\left(\frac{\omega(k - 1)}{2}\right)} e^{-i\left(\frac{\omega(k - 1)}{2}\right)\theta},
\]
\[
= i\sqrt{\left(2q \cos\left(\frac{\omega(k - 1)}{2}\right)\right)^2 - (a - 1)^2 + (1 - a) + 2q \cos\left(\frac{\omega(k - 1)}{2}\right)} e^{-i\left(\frac{\omega(k - 1)}{2}\right)\theta} \times
\]
\[
\cos\left(\arccos\left(\frac{a - 1}{2q \cos\left(\frac{\omega(k - 1)}{2}\right)}\right)\right) - i\sin\left(\arccos\left(\frac{a - 1}{2q \cos\left(\frac{\omega(k - 1)}{2}\right)}\right)\right)
\]
\[
= i\sqrt{\left(2q \cos\left(\frac{\omega(k - 1)}{2}\right)\right)^2 - (a - 1)^2 - i\sqrt{\left(2q \cos\left(\frac{\omega(k - 1)}{2}\right)\right)^2 - (a - 1)^2},
\]
\[
= 0.
\]
Thus, this implies that \(i\gamma\) is a root of (3.1). Similarly, in the case \(\omega < 0\), it can be shown that \(- i\gamma\) is a root of (3.1) for the sum of delays \((k_n + l_n)^-\). The proof is completed.

When \(q > 0\), we have the following analogous result.

**Lemma 4.** Suppose that, \(q < 0\) and \(0 < \theta \leq \frac{x}{2}\). Let \(k = i\omega\) be a root of (3.1) where \(\omega \in \left(\frac{x}{2}, \frac{x}{2}\right) - \left\{-\frac{\omega n_1 k_1}{4}, \frac{\omega n_2 k_2}{4}\right\}\) for \(n = 1, 2, \ldots\), then the following conditions hold:
(i) If \( (2q \cos \left( \frac{\omega}{k-\theta} \right) )^2 - (a - 1)^2 \leq 0 \), then there exists no real number \( \omega \).

(ii) If \( (2q \cos \left( \frac{\omega}{k-\theta} \right) )^2 - (a - 1)^2 > 0 \), then the real numbers \( \omega \), \( q \) and the delays \( (k + l) \) are as follows:

\[
\omega = \pm \gamma = \pm \sqrt{\left( 2q \cos \left( \frac{\omega}{k-\theta} \right) \right)^2 - (a - 1)^2},
\]

\( q = \frac{2 \cos \left( \frac{\omega}{k-\theta} \right) - (a - 1)^2}{2q \cos \left( \frac{\omega}{k-\theta} \right)} \) and \( k + l = (a_n + \beta_n)^\pm \) for \( n = 0, 1, 2, \ldots \), where \((a_n + \beta_n)^+\) and \((a_n + \beta_n)^-\):

\[
(a_n + \beta_n)^+ = \frac{2}{\gamma} \left\{ 2n\pi - \arccos \left( \frac{a - 1}{2q \cos \left( \frac{\omega}{k-\theta} \right)} \right) + \theta \right\},
\]

\[
(a_n + \beta_n)^- = \frac{2}{\gamma} \left\{ (2n + 2)\pi - \arccos \left( \frac{a - 1}{2q \cos \left( \frac{\omega}{k-\theta} \right)} \right) - \theta \right\},
\]

and \( i\gamma \) or \(- i\gamma\) is a root of (3.1) for the sum of delays \((a_n + \beta_n)^+\) or \((a_n + \beta_n)^-\).

**Proof.** The proof is similar to Lemma 3.

**Remark 1.** For \( q > 0 \), from the definitions of \((k_n + l_n)^\pm\):

\[
\min \left\{ k_n + l_n^\pm : n = 0, 1, \ldots \right\} = \begin{cases} (k_0 + l_0^-) & \text{if } (a - 1) - 2q \cos \theta \cos \left( \frac{\omega}{k-\theta} \right) < 0 \\ (k_0 + l_0^+) & \text{if } (a - 1) - 2q \cos \theta \cos \left( \frac{\omega}{k-\theta} \right) \geq 0, \end{cases}
\]

is obtained. Similarly, for \( q < 0 \), we obtain from the definitions of \((a_n + \beta_n)^\pm\) as follows:

\[
\min \left\{ (a_n + \beta_n)^\pm : n = 0, 1, \ldots \right\} = \begin{cases} (a_0 + \beta_0)^+ & \text{if } (a - 1) - 2q \cos \theta \cos \left( \frac{\omega}{k-\theta} \right) < 0 \\ (a_0 + \beta_0)^- & \text{if } (a - 1) - 2q \cos \theta \cos \left( \frac{\omega}{k-\theta} \right) \geq 0. \end{cases}
\]

**Lemma 5.** Suppose that \( 0 < \theta \leq \frac{\pi}{2} \), \( \omega \in (\frac{-\pi}{k-\theta}, \frac{\pi}{k-\theta}) - \{0\} \) and

\[
a^2 + q^2\omega(k + l) \sin(\omega(l - k)) > 0.
\]

Also, the following conditions

\[
\begin{align*}
\frac{\sin(\omega k - \theta)}{\sinh(k - \theta)} > q & \text{ if } \frac{\omega}{\theta} > 0 & \frac{\sin(\omega k - \theta)}{\sinh(k - \theta)} < q & \text{ if } \frac{\omega}{\theta} < 0 \\
\frac{\sin(\omega k - \theta)}{\sinh(k - \theta)} > q & \text{ if } \frac{\omega}{\theta} < 0 & \frac{\sin(\omega k - \theta)}{\sinh(k - \theta)} < q & \text{ if } \frac{\omega}{\theta} > 0,
\end{align*}
\]

are provided. Then all the roots of Equation (3.1) on the imaginary axis move in the right half-plane as \( k \) and \( l \) increase.

**Proof.** Let \( \lambda = i\omega \) be a root of (3.1) where \( \omega \in (\frac{-\pi}{k-\theta}, \frac{\pi}{k-\theta}) - \{0\} \) is a real number. It will be enough to show

\[
\Re \left| \frac{\partial \lambda}{\partial k} \right| > 0 \quad \text{and} \quad \Re \left| \frac{\partial \lambda}{\partial l} \right| > 0.
\]

Firstly, we take the derivative of \( \lambda \) with respect to \( k \) on Equation (3.1), we have

\[
\frac{\partial \lambda}{\partial k} - q\omega e^{ik\omega} - qk\omega e^{-ik\omega} \frac{\partial \lambda}{\partial k} - q\omega e^{i\omega} \frac{\partial \lambda}{\partial k} = 0.
\]
\[
\frac{\partial \lambda}{\partial k} = \frac{q \lambda e^{-i\theta k} + i \theta}{1 - q (e^{-i\theta k} + le^{-i\theta l})}.
\]

Substituting \(\lambda = i\omega\) into the above equation, we obtain
\[
\frac{\partial \lambda}{\partial k} \bigg|_{\lambda = i\omega} = \frac{i\omega + 1 - a}{1 - q (e^{-i\theta k} + le^{-i\theta l})} = \frac{i\omega + 1 - a}{1 - q (k \cos(\omega k - \theta) + l \cos(\omega l + \theta)) + iq (k \sin(\omega k - \theta) + l \sin(\omega l + \theta))}.
\]

If we multiply with the complex conjugate of the denominator in the above equation, then we can write
\[
\text{Re} \left( \frac{\partial \lambda}{\partial k} \right) \bigg|_{\lambda = i\omega} = \frac{\omega \sin(\omega l - \theta) - q^2 \omega l \sin(\omega (k - l))}{M},
\]
where
\[
M = (1 - q (k \cos(\omega k - \theta) + l \cos(\omega l + \theta)))^2 + q^2 (k \sin(\omega k - \theta) + l \sin(\omega l + \theta))^2.
\]

Since (3.11), we can write \(\text{Re} \frac{\partial \lambda}{\partial k} \bigg|_{\lambda = i\omega} > 0\). On the other hand, we take the derivative of \(\lambda\) with respect to \(l\) on Equation (3.1), similar to (3.12)
\[
\text{Re} \left( \frac{\partial \lambda}{\partial l} \right) \bigg|_{\lambda = i\omega} = \frac{\omega \sin(\omega l - \theta) - q^2 \omega k \sin(\omega (k - l))}{M},
\]
is obtained. From (3.11), we obtain \(\text{Re} \frac{\partial \lambda}{\partial l} \bigg|_{\lambda = i\omega} > 0\). Moreover, by adding both (3.12) and (3.13) together, we have
\[
\text{Re} \left( \frac{\partial \lambda}{\partial k} \right) \bigg|_{\lambda = i\omega} + \text{Re} \left( \frac{\partial \lambda}{\partial l} \right) \bigg|_{\lambda = i\omega} = \frac{\omega^2 + q^2 \omega (k + l) \sin(\omega (l - k))}{M} > 0.
\]
Hence, the proof is completed.

Now we can state and prove main theorems.

4. Main results
We will show that the stability analysis with a qualitative approach, as we have already mentioned in section 1.

**Theorem 1.** Suppose that \(0 < \theta \leq \frac{\pi}{4}\) and the conditions of Lemma 5 are satisfied. Let the matrix \(A\) of system (1.1) be in the form (II). Then system (1.1) is asymptotically stable if and only if either
\[
\begin{cases}
(a - 1) - 2q \cos \theta \cos \left(\frac{\omega (k - l)}{2}\right) < 0 \\
2q \cos \left(\frac{\omega (k - l)}{2}\right)^2 - (a - 1)^2 \leq 0.
\end{cases}
\]  
(4.1)

or
\[
\begin{cases}
(a - 1) - 2q \cos \theta \cos \left(\frac{\omega (k - l)}{2}\right) < 0 \\
2q \cos \left(\frac{\omega (k - l)}{2}\right)^2 - (a - 1)^2 > 0 \\
k + l < \frac{2 \text{sgn}(q)}{\sqrt{2q \cos \left(\frac{\omega (k - l)}{2}\right)^2 - (a - 1)^2}} \left\{\arccos \left(\frac{a - 1}{2q \cos \left(\frac{\omega (k - l)}{2}\right)}\right) - \theta\right\}
\end{cases}
\]  
(4.2)
Proof. In the case of \( k = 0 \) and \( l = 0 \), the root of (3.1) is only \( \lambda_j(0,0) = a - 1 - 2b \cos \theta - i2b \sin \theta \). Thus, the root of the Equation (3.1) has a negative real part. By the continuity of the roots with respect to \( k \) and \( l \), we can say that all the roots of (3.1) lie in the left half plane for \( k > 0 \) and \( l > 0 \) sufficiently small.

For the sufficiency, here our claim is: If either condition (4.1) or (4.2) holds, then (3.1) does not have a root on the imaginary axis. By condition (4.1) and Lemma 3, our claim is true for \( k > 0 \) and \( l > 0 \). Now, suppose that condition (4.2) holds: Since

\[
\frac{2 \text{sgn}(q)}{\sqrt{\left(2q \cos \left(\frac{\alpha(k-l)}{2}\right)\right)^2 - (a-1)^2}} \left\{ \arccos \left( \frac{a-1}{2q \cos \left(\frac{\alpha(k-l)}{2}\right)} \right) - \theta \right\} = \begin{cases} (k_0 + l_0)^- & \text{if } q > 0 \\ (a_0 + b_0)^+ & \text{if } q < 0, \end{cases}
\]

and Remark 1, we obtain \( (k+l) \neq (k_n + l_n)^k \), \( (k+l) \neq (a_n + b_n)^k \) for \( n = 0, 1, 2, \ldots \). Thus, we obtain the contraposition with Lemma 1, our other claim is also true. By the above argument and Lemma 2, we can say that if either condition (4.1) or (4.2) holds, then all the roots of (3.1) lie in the left half plane.

For the necessity, we will show the following contraposition: either

\[
(a - 1) - 2q \cos \theta \cos \left(\frac{\alpha(k-l)}{2}\right) \geq 0,
\]

or

\[
\left\{ \begin{array}{l} k + l \geq \frac{2 \text{sgn}(q)}{\sqrt{\left(2q \cos \left(\frac{\alpha(k-l)}{2}\right)\right)^2 - (a-1)^2}} \left\{ \arccos \left( \frac{a-1}{2q \cos \left(\frac{\alpha(k-l)}{2}\right)} \right) - \theta \right\} \end{array} \right\}.
\]

Thus, if (4.3) and (4.4) hold, then there exists roots \( \lambda_j \) of (3.1) such that \( \text{Re}(\lambda_j) > 0 \) for \( j = 1, 2 \). Assume that (4.3) holds and let \( \lambda_j(k,l) \) be the branch of the root of satisfying \( \lambda_j(0,0) = a - 1 - 2b \cos \theta - i2b \sin \theta \). Then, Lemma 5 or the continuity of \( \lambda_j(k,l) \) implies that \( \text{Re}(\lambda_j) > 0 \) for \( k > 0 \) and \( l > 0 \) sufficiently small. From here, we can say that \( \lambda_j(k,l) \) cannot move in the left half-plane crossing on the imaginary axis as \( k \) and \( l \) increase. Hence, we have \( \text{Re}(\lambda_j) > 0 \) for all \( k > 0 \) and \( l > 0 \). Assume that (4.4) holds and let \( \lambda_j(k,l) \) be the branch of the root of satisfying \( \lambda_j(k_0,l_0) = -i \text{sgn}(q) \sqrt{\left(2q \cos \left(\frac{\alpha(k-l)}{2}\right)\right)^2 - (a-1)^2} \). Then, Lemma 5 or the continuity of \( \lambda_j(k,l) \) implies that \( \text{Re}(\lambda_j) > 0 \) for \( k - k_0 > 0 \) and \( l - l_0 > 0 \) sufficiently small. From here, we can say that \( \lambda_j(k,l) \) cannot move in the left half-plane crossing on the imaginary axis as \( k \) and \( l \) increase. Hence, we have \( \text{Re}(\lambda_j) > 0 \) for all \( k > k_0 \) and \( l > l_0 \).

The proof is completed.

**Remark 2.** We consider the delay differential system (1.1) where matrix \( A \) is given as in case (I), i.e.,

\[
x' + (1-a)x(t) + \begin{pmatrix} q_1 & r \\ 0 & q_2 \end{pmatrix} x(t-k) + x(t-l) = 0, \quad t \geq 0.
\]

Then, characteristic equation of (4.5) is as follows:

\[
(\lambda + (1-a) + q_1(e^{-jk} + e^{-il})) (\lambda + (1-a) + q_2(e^{-jk} + e^{-il})) = 0.
\]

It is obvious that for \( a = 1 \) and \( i = 1, 2 \), the equation \( \lambda + q_i(e^{-jk} + e^{-il}) = 0 \) is the characteristic equation of (4.6) with \( q = q_i \), and so one can immediately obtain the following corollary from the previous result given by Kuang (1993).
Corollary 1. Suppose that \( a = 1 \) for system (4.6). Let the matrix \( A \) of system (4.6) is written as the form (1). Then system (4.6) is asymptotically stable if and only if for \( i = 1, 2 \)

\[
2q_i(k + l) \cos \left( \frac{k - l \pi}{k + 1} \right) < \pi.
\]

(4.7)

Theorem 2. Suppose that conditions of Lemma 5 are satisfied. Let the matrix \( A \) of system (1.1) be in the form (1). Then system (1.1) is asymptotically stable if and only if for \( i = 1, 2 \) either

\[
\left\{ \begin{array}{l}
(\alpha - 1) - 2q_i \cos \left( \frac{q_i k - l}{q_i} \right) < 0 \\
\left( 2q_i \cos \left( \frac{q_i k - l}{q_i} \right) \right) - (\alpha - 1)^2 \leq 0.
\end{array} \right.
\]

or

\[
\left\{ \begin{array}{l}
(\alpha - 1) - 2q_i \cos \left( \frac{q_i k - l}{q_i} \right) < 0 \\
\left( 2q_i \cos \left( \frac{q_i k - l}{q_i} \right) \right) - (\alpha - 1)^2 > 0 \\
k + l < \frac{2 \text{sgn}(q_i)}{\sqrt{(2q_i \cos \left( \frac{q_i k - l}{q_i} \right))} - (\alpha - 1)^2} \left\{ \arccos \left( \frac{\alpha - 1}{2q_i \cos \left( \frac{q_i k - l}{q_i} \right)} \right) \right\}. \tag{4.9}
\end{array} \right.
\]

Proof. The proof is similar to Theorem 1.

5. An extension to a system of higher dimension

Finally, a higher dimensional linear delay differential system with two delays is considered

\[
x'(t) + (1 - a)x(t) + A(x(t - k) + x(t - l)) = 0 \quad t \geq 0.
\]

(5.1)

where \( a \) is a real number, \( A \) is a \( d \times d \) real constant matrix, and \( k, l \) are positive numbers such that \( k > l \).

Theorem 3. Let \( q_j e^{i\theta_j} (j = 1, 2, \ldots, d) \) be the eigenvalues of matrix \( A \). Then system (5.1) is asymptotically stable iff

\[
\left\{ \begin{array}{l}
(\alpha - 1) - 2q_i \cos \theta_j \cos \left( \frac{q_i k - l}{q_i} \right) < 0 \\
\left( 2q_i \cos \left( \frac{q_i k - l}{q_i} \right) \right) - (\alpha - 1)^2 \leq 0.
\end{array} \right.
\]

(5.2)

or

\[
\left\{ \begin{array}{l}
(\alpha - 1) - 2q_i \cos \theta_j \cos \left( \frac{q_i k - l}{q_i} \right) < 0 \\
\left( 2q_i \cos \left( \frac{q_i k - l}{q_i} \right) \right) - (\alpha - 1)^2 > 0 \\
k + l < \frac{2 \text{sgn}(q_i)}{\sqrt{(2q_i \cos \left( \frac{q_i k - l}{q_i} \right))} - (\alpha - 1)^2} \left\{ \arccos \left( \frac{\alpha - 1}{2q_i \cos \left( \frac{q_i k - l}{q_i} \right)} \right) - \theta_j \right\}. \tag{5.3}
\end{array} \right.
\]

where \( q_i, \theta_j \) are real numbers and \( |\theta_j| \leq \frac{\pi}{2} \).

Proof. Since \( q_j e^{i\theta_j} (j = 1, 2, \ldots, d) \) be the eigenvalues of matrix \( A' \) the characteristic equation of system (5.1) is given by

\[
f(\lambda) = \prod_{j=1}^{d} \left( \lambda + (1 - a) + q_j \left( e^{y k + i|\theta_j|} + e^{y l - i|\theta_j|} \right) \right) = 0.
\]

Thus, Theorem 3 can be seen as a result of Theorems 1 and 3.
